# Food Delivery Delay Analysis

A comprehensive investigation into the root causes of delivery delays and actionable strategies to improve on-time performance

Made with GAMMA

# Executive Summary

## The Core Finding

Restaurant preparation time emerges as the dominant factor influencing delivery delays. Approximately **61%** of orders were delayed, indicating a systemic operational challenge rather than isolated incidents.

The analysis revealed a critical threshold: orders with preparation times exceeding **30 minutes** were almost always delayed, while orders prepared within this threshold were delivered on time in the majority of cases—even during adverse conditions such as rainy weather and peak hours.

Key implication: Improving restaurant preparation efficiency can significantly reduce delivery delays, potentially outweighing the impact of external factors such as weather and demand surges.

Made with GAMMA

# Business Problem

## Why This Matters

Delayed food deliveries create a cascade of negative impacts that erode platform performance and customer trust. Understanding the root causes is essential for operational planning.

### Customer Satisfaction

Delayed orders frustrate customers, leading to negative reviews and reduced loyalty

### Platform Reputation

Consistent delays damage brand perception and competitive positioning

### Operational Efficiency

Delays reveal inefficiencies that increase costs and reduce delivery capacity

### Revenue Impact

Customer churn and negative word-of-mouth directly affect top-line growth

## Our Objectives

- **Quantify the extent of delivery delays** across the platform
- **Identify primary contributors** to these delays using data analysis
- **Evaluate impact** of weather and peak-hour demand conditions
- **Provide actionable insights** to measurably improve on-time delivery performance

Made with GAMMA

# Data Overview

## Dataset Profile

A synthetic dataset was created to simulate realistic food delivery operations, enabling controlled analysis without real-world data constraints.

**Record Count:** 500 orders

**Purpose:** Learning and operational analysis

**Representativeness:** Mimics real-world delivery scenarios and constraints

## Key Variables Analyzed

| Variable | Description | Purpose |
|---|---|---|
| order_id | Unique identifier for each order | Tracking and grouping |
| restaurant_prep_time | Time taken by restaurant to prepare the order (minutes) | Critical operational metric |
| delivery_time | Time taken to deliver the order (minutes) | Performance measurement |
| distance_km | Distance between restaurant and customer | Route complexity analysis |
| weather | Weather condition (Clear / Rain) | External condition impact |
| peak_hour | Whether the order was placed during peak hours (Yes / No) | Demand analysis |
| delayed | Delivery outcome (1 = Delayed, 0 = On-time) | Primary outcome variable |

Made with GAMMA

# Methodology

The analysis followed a structured Exploratory Data Analysis (EDA) approach, focusing on pattern recognition and operational interpretation rather than predictive modeling.

01

### Data Validation

Initial quality checks and data integrity verification

02

### Delay Rate Calculation

Quantify overall percentage of delayed orders

03

### Comparative Analysis

Compare preparation time between delayed and on-time orders

04

### Threshold Identification

Determine critical preparation time limits for success

05

### Conditional Assessment

Control for preparation time while evaluating other factors

06

### Secondary Factor Analysis

Assess impact of weather and peak-hour demand

07

### Operational Interpretation

Translate findings into actionable insights

**Strategic Focus:** The methodology prioritized understanding operational patterns and their business impact, ensuring findings translate directly to improved delivery performance rather than theoretical statistical relationships.

Made with GAMMA

# Analysis & Findings: The Big Picture

**61%**

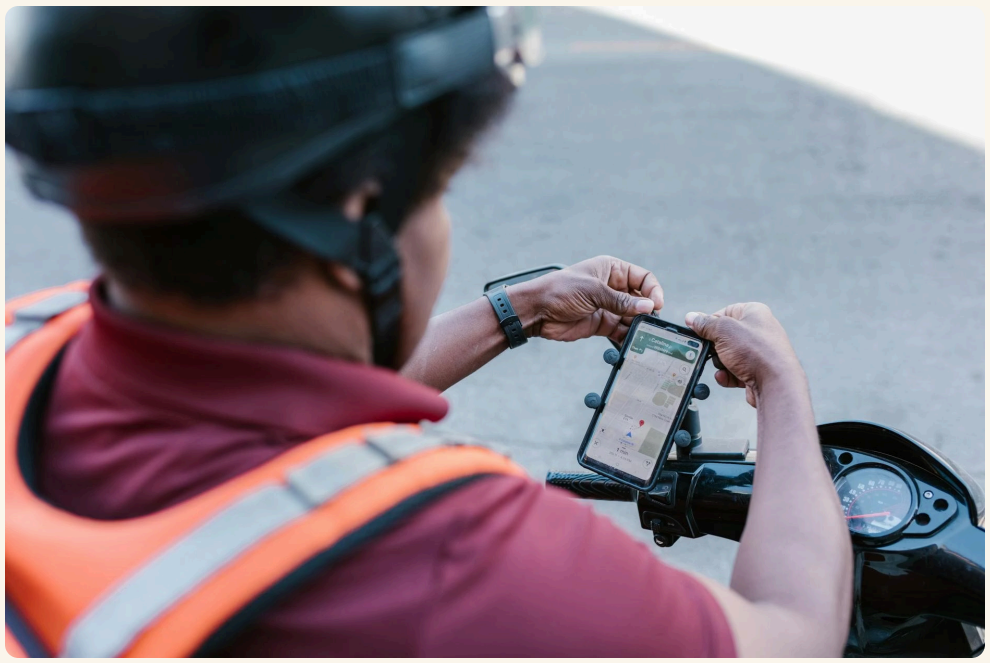
Overall Delay Rate

Delayed orders represent the majority, not the exception

**13+**

Additional Minutes

Average extra preparation time for delayed orders



**30**

Critical Threshold

Minutes that determines delivery success or failure

## Widespread Challenge

The **61% delay rate** indicates systemic operational issues rather than isolated incidents. This widespread problem confirms the need for fundamental operational improvements rather than targeted fixes.

## Preparation Time: The Dominant Factor

### On-Time Orders: ~19.5 min

Average preparation time for orders that arrived on schedule

### Delayed Orders: ~33.0 min

Average preparation time for orders that missed their delivery window

This **~13.5 minute gap** represents the operational efficiency difference between delivery success and failure, directly implicating restaurant preparation processes as the primary bottleneck.

Made with GAMMA

# Threshold Analysis: The 30-Minute Rule

## Preparation Time vs. Delay Likelihood

A threshold analysis was conducted to quantify delay probability at different preparation time levels. The results reveal a stark inflection point that divides delivery success from failure.

| Preparation Time | Delay Rate | On-Time Rate |
|---|---|---|
| ⩽ 30 minutes | ~28% | **~72%** |
| > 30 minutes | **~100%** | ~0% |

### Orders ⩽ 30 Minutes

When restaurants prepare orders within 30 minutes, the majority (~72%) arrive on time despite external conditions. This demonstrates that efficient preparation can overcome weather and peak-hour challenges.

### Orders > 30 Minutes

When preparation exceeds 30 minutes, delays become virtually guaranteed (~100%), regardless of delivery rider performance or route efficiency.

**Key Insight:** The 30-minute threshold serves as a critical operational benchmark. Orders that clear this bar have a fighting chance; those that don't face almost certain delays.

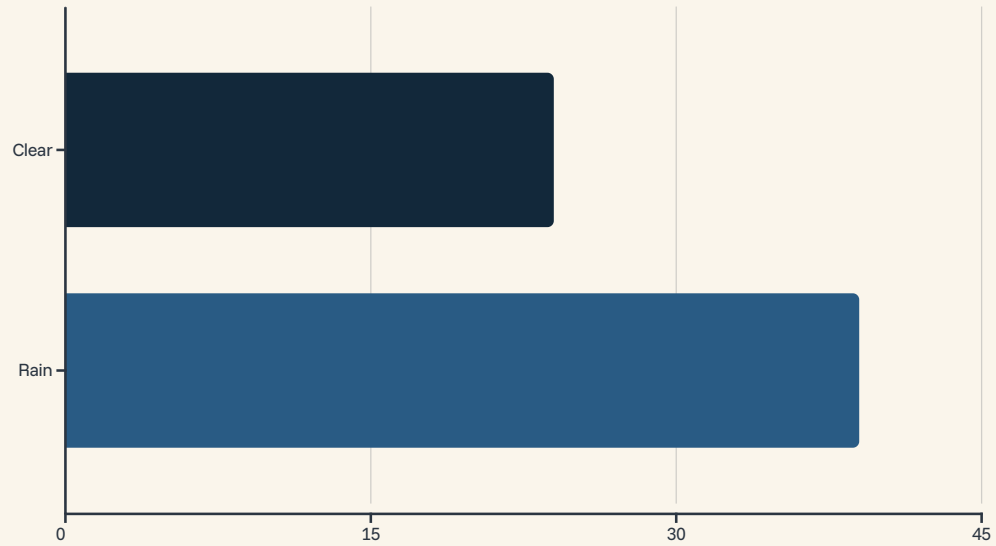
Made with GAMMA

# External Factors: Weather and Peak Hours

To isolate the impact of external conditions, both analyses controlled for preparation time, examining only orders prepared within 30 minutes.

## Weather Impact Analysis

**Context:** Controlling for preparation time ⩽ 30 minutes

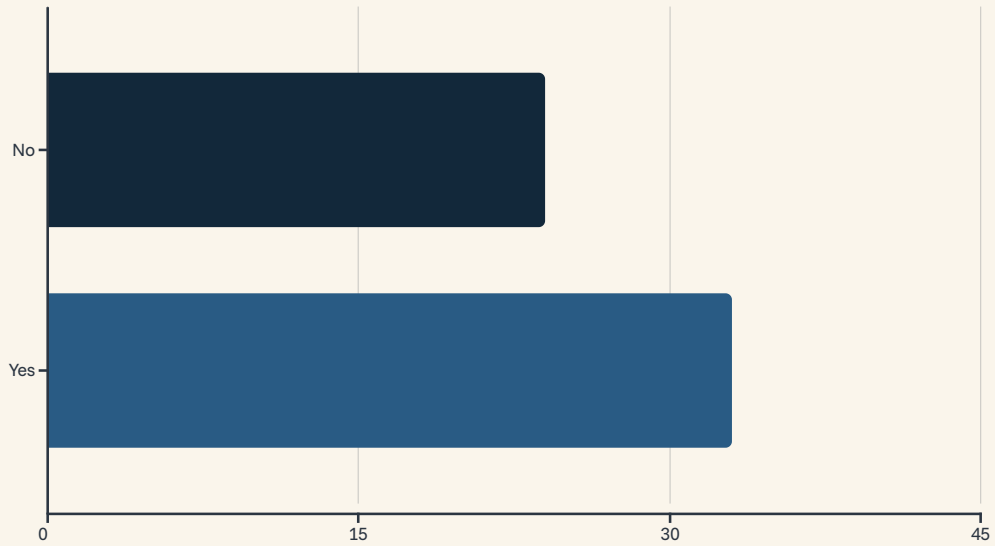


Adverse weather conditions increase the probability of delays by **~15 percentage points**.

Key Finding: Even under rainy conditions, over 60% of orders are delivered on time when preparation time remains under control.

## Peak Hour Impact Analysis

**Context:** Controlling for preparation time ⩽ 30 minutes



Peak-hour demand increases the likelihood of delays by **~9 percentage points**.

Key Finding: Timely restaurant preparation still ensures that the majority of orders (~67%) are delivered on time during high-demand periods.

**Overall Conclusion:** While weather and peak-hour demand are non-trivial factors, their impact is dwarfed by restaurant preparation efficiency. When orders are prepared quickly, external conditions become manageable challenges rather than delivery failures.

# Business Recommendations

Based on the analysis findings, here are prioritized actions to reduce delivery delays and improve customer satisfaction:

## Enforce Preparation Time SLAs

Establish a strict **30-minute preparation threshold** as a contractual commitment with partner restaurants. This becomes the non-negotiable operational standard.

- Build automatic penalty/reward mechanisms
- Create tiered restaurant partnerships based on performance
- Use the threshold as a qualification criterion for new partners

## Real-Time Monitoring System

Implement continuous tracking of preparation times with automatic alerts as orders approach the 30-minute threshold.

- Generate rider dispatch alerts at 25 minutes
- Notify customers of potential delays at 28 minutes
- Escalate to restaurant management at 30 minutes

## Dynamic Resource Allocation

Anticipate increased delivery capacity needs during rainy conditions and peak hours, but base resource planning on preparation time realities.

- Pre-position riders at high-volume restaurants
- Implement surge pricing during weather events
- Create dedicated delivery pools for peak periods

## Restaurant Performance Tracking

Systematically identify consistently underperforming restaurants and provide operational support or incentives to improve efficiency.

- Monthly performance dashboards for all partners
- Operational coaching for restaurants exceeding 30 minutes
- Incentive programs for restaurants maintaining <25 minutes

**Implementation Priority:** Start with SLA enforcement and monitoring systems, as these deliver immediate operational benefits. Resource allocation and performance tracking can be phased in over subsequent months.

Made with GAMMA

# Conclusion & Next Steps

## Key Takeaways

This analysis demonstrates that **restaurant preparation efficiency** is the most effective lever for reducing food delivery delays.

While external factors such as weather and peak-hour demand influence delivery performance, their impact is significantly mitigated when preparation times are kept under control.

Focusing on operational efficiency at the restaurant level can substantially improve customer experience and delivery reliability.

## Implementation Roadmap

1. Deploy monitoring dashboards (Week 1-2)
2. Implement SLA enforcement (Week 3-6)
3. Build resource allocation models (Week 7-10)
4. Launch restaurant performance program (Week 11-14)
5. Measure baseline performance and track monthly progress (Week 15+)

## Key Assumptions

- Prep time directly affects delivery readiness
- Rider availability is assumed constant
- No order batching considered

## Areas for Future Analysis

### Rider Availability Factors

Map delivery capacity to demand patterns, incorporating time-of-day, day-of-week, and seasonal variations

### Traffic Conditions

Integrate real-time traffic data with historical congestion patterns to refine delivery time estimates

### Order Batching

Analyze optimal groupings of orders to minimize wait times while respecting individual delivery windows

*Note: This analysis used synthetic data for learning purposes. Real-world implementation should validate findings against actual operational data.*
